Download and load the dataset

You can follow along by downloading and loading the dataset by placing the following *setup* code block at the top of a R Markdown file.

```
```{r setup, include = FALSE}
Load required packages
library(tidyverse)
library(infer)
Load dataset
applicants_data <- read_rds(
 url("http://data.cds101.com/gender_discrimination.rds")
)
Observed result
experiment_result <- (21/24) - (14/24)
````</pre>
```

Recap of gender discrimination dataset

- Experiment involving 48 male bank supervisors that were each given the same personnel file and asked to judge whether the person should be promoted to a branch manager job that was described as "routine"
- The files were identical except that half of the supervisors had files showing the person was male while the other half had files showing the person was female
- It was randomly determined which supervisors got "male" applications and which got "female" applications
- Result: 29.2% more men than women were recommended for promotion

Is this result statistically significant?

Null and alternative hypothesis

Null hypothesis

Promotion and gender are **independent**, no gender discrimination, observed difference in proportions is simply due to chance.

 $H_0 {:} \, \frac{Promoted \; Men}{Total \; Men} - \frac{Promoted \; Women}{Total \; Women} = 0$

Alternative hypothesis

Promotion and gender are **dependent**, men are more likely to be promoted than women due to gender discrimination, observed difference in proportions is not due to chance.

$$H_A \text{:} \frac{Promoted \ Men}{Total \ Men} - \frac{Promoted \ Women}{Total \ Women} > 0$$

We need to generate a null distribution in order to perform a hypothesis test. In a previous video, we saw how to do this using a deck of playing cards. Now we will do the same thing using R using the infer package:

```
simulation_results <- applicants_data %>%
  specify(outcome ~ sex, success = "Promoted") %>%
  hypothesize(null = "independence") %>%
  generate(reps = 10000, type = "permute") %>%
  calculate(stat = "diff in props", order = combine("Male", "Female"))
```

```
simulation_results <- applicants_data %>%
    specify(outcome ~ sex, success = "Promoted") %>%
    hypothesize(null = "independence") %>%
    generate(reps = 10000, type = "permute") %>%
    calculate(stat = "diff in props", order = combine("Male", "Female"))
```

 In specify(outcome ~ sex, success = "Promoted"), the first part outcome ~ sex is a formula where the lefthand variable outcome is the response and the righthand variable sex is explanatory.

```
simulation_results <- applicants_data %>%
  specify(outcome ~ sex, success = "Promoted") %>%
  hypothesize(null = "independence") %>%
  generate(reps = 10000, type = "permute") %>%
  calculate(stat = "diff in props", order = combine("Male", "Female"))
```

- In specify(outcome ~ sex, success = "Promoted"), the first part outcome ~ sex is a formula where the lefthand variable outcome is the response and the righthand variable sex is explanatory.
- In hypothesize(null = "independence"), we specify that we will simulate what will happen if outcome and sex were independent.

```
simulation_results <- applicants_data %>%
  specify(outcome ~ sex, success = "Promoted") %>%
  hypothesize(null = "independence") %>%
  generate(reps = 10000, type = "permute") %>%
  calculate(stat = "diff in props", order = combine("Male", "Female"))
```

- In specify(outcome ~ sex, success = "Promoted"), the first part outcome ~ sex is a formula where the lefthand variable outcome is the response and the righthand variable sex is explanatory.
- In hypothesize(null = "independence"), we specify that we will simulate what will happen if outcome and sex were independent.
- In generate(reps = 10000, type = "permute"), we specify that we will run 10,000 simulations by permuting the outcome and sex columns
- To permute, we randomly shuffle the data in the outcome column, and then randomly shuffle the data in the sex column

```
simulation_results <- applicants_data %>%
  specify(outcome ~ sex, success = "Promoted") %>%
  hypothesize(null = "independence") %>%
  generate(reps = 10000, type = "permute") %>%
  calculate(stat = "diff in props", order = combine("Male", "Female"))
```

 Using calculate(stat = "diff in props", order = combine("Male", "Female")) means, after each simulation, compute:

Promoted Men	Promoted Women
Total Men	Total Women

Note that this expression is exactly how experiment_result was calculated.

Visualizing the null distribution

```
simulation_results %>%
visualize(bins = 9) +
shade_p_value(obs_stat = experiment_result, direction = "right") +
labs(
   title = "Gender discrimination null distribution",
   x = "difference in fraction of male and female promotions"
)
```

Probability of randomly getting result

One way we can quantify the probability that the experiment's result is due to statistical variance is to compute how much of the null distribution represents outcomes that are the same or more extreme than the actual experiment:

```
simulation_results %>%
filter(stat >= experiment_result) %>%
summarize(random_result_probability = n() / 10000)
```

random_result_probability

0.0227

This value is called the *p*-value, and can be obtained directly using infer:

```
simulation_results %>%
  get_p_value(obs_stat = experiment_result, direction = "right")
```

p_value

0.0227

Conclusions from our simulation

Do the results of the simulation provide convincing evidence of gender discrimination against women, i.e. dependence between gender and promotion decisions?

- 1. No, the data do not provide convincing evidence for the alternative hypothesis, therefore we can't reject the null hypothesis of independence between gender and promotion decisions. The observed difference between the two proportions was due to chance.
- 2. Yes, the data provide convincing evidence for us to reject the null hypothesis in favor of the alternative hypothesis of gender discrimination against women in promotion decisions. The observed difference between the two proportions was due to a real effect of gender.

Conclusions from our simulation

Do the results of the simulation provide convincing evidence of gender discrimination against women, i.e. dependence between gender and promotion decisions?

- 1. No, the data do not provide convincing evidence for the alternative hypothesis, therefore we can't reject the null hypothesis of independence between gender and promotion decisions. The observed difference between the two proportions was due to chance.
- 2. Yes, the data provide convincing evidence for us to reject the null hypothesis in favor of the alternative hypothesis of gender discrimination against women in promotion decisions. The observed difference between the two proportions was due to a real effect of gender.
